MICROSTRUCTURE AND MICROANALYSIS (SEM/EDX) DETERMINATION OF GLASSES FROM MALLORCA AND MENORCA CAVES (1)

*DETERMINACION DE LA MICROESTRUCTURA
Y MICROANALISIS (SEM/EDX) DE VIDRIOS
PROCEDENTES DE CUEVAS DE MALLORCA
Y MENORCA*

JESUS MARIA RINCON (*)

ABSTRACT

In recent years a field of research of growing interest has been the application of physico-chemical characterization methods on modern materials to the study of ancient materials found by the archaeologists. This new field on Materials Science is known as Archaeometry. Many questions about the origin and manufacture of ancient glasses can be solved by using the same methods of analysis and microstructure characterization applied normally to special and advanced glasses.

The islands of Mallorca and Menorca, located in the Balearic archipelago in the Mediterranean sea, has long been a crossing place of cultures. Transparent, opal and coloured glasses have been found in various archaeological investigations carried out in these islands. In order to know the composition and microstructure of some of these glasses, an archaeometric study has been carried out using X-ray diffraction (XRD), transmission electron microscopy (TEM), scanning electron microscopy and energy-dispersive X-ray analysis (SEM/EDX), differential thermal analysis (DTA), and hot stage optical microscopy (HSM) methods.

The SEM/EDX average microanalysis results show

that these glasses are deficient in sodium and highly enriched in Al_2O_3 and Fe_2O_3 , their composition being in the range: 0.5-1.5 K_2O , 8-10 CaO , 6-8 Al_2O_3 , 6-8 Fe_2O_3 , 74-76 SiO_2 (wt %). Some of these glasses also contain high percentages of lead. Small quantities of TiO_2 , CuO and SO_3 (0.5 %) have also been detected. Surface decoration and blue colour are other features of these ancient glasses, the surface of which, depicted by SEM, is highly altered with flaked and corroded microstructures.

RESUMEN

En los últimos años la aplicación de los métodos físico-químicos de caracterización de materiales modernos al estudio de materiales antiguos es un campo de investigación de creciente interés para los arqueólogos. Este nuevo campo de investigación en Ciencia de los Materiales se viene denominando con el nombre de Arqueometría. Por lo tanto, muchas cuestiones sobre el origen y manufactura de los vidrios antiguos pueden resolverse usando los mismos métodos de análisis y de caracterización microestructural que se aplican normalmente a vidrios especiales o avanzados.

La isla de Mallorca ha sido en el pasado un lugar de paso y de encuentro de diferentes culturas. Se han encontrado vidrios transparentes, opalescentes y coloreados en diferentes

investigaciones arqueológicas llevadas a cabo en esta isla del Mediterráneo.

Para conocer la composición y microestructura de algunos vidrios encontrados en cuevas de Mallorca y Menorca se ha realizado, pues, un estudio arqueométrico por las técnicas de: Difracción de rayos X (DRX); microscopía electrónica de Transmisión (MET), microscopía electrónica de barrido y microanálisis por dispersión de energías de rayos X (MEB/EDX), análisis térmico diferencial (ATD) y microscopía de calefacción (HSM). Los resultados de MEB/EDX de microanálisis promedio muestran que estos vidrios son deficientes en sodio y altamente enriquecidos en Al_2O_3 y Fe_2O_3 estando su composición en el intervalo: 0,5-1,5 K_2O , 8-10 CaO , 6-8 Al_2O_3 , 6-8 Fe_2O_3 , 74-76 SiO_2 (% peso). Algunos de estos vidrios también contienen un alto porcentaje de plomo. Se han detectado pequeñas cantidades de TiO_2 , CuO y SO_3 (< 0,5 %). La superficie decorada, el color azul y las otras características de estos vidrios que muestran su superficie altamente corroída por MEB han sido también analizados y discutidos.

Key words: Ancient glasses. Archaeometry. Mallorca island. Scanning electron microscopy. X-Ray microanalysis.

Palabras clave: Vidrios antiguos. Arqueometría. Mallorca. Microscopía electrónica. Microanálisis.

INTRODUCTION

The Balearic islands, located in the Mediterranean sea, have been influenced in the past by several cultures. They were places of passage and foci of important commercial activities. In the larger islands, Mallorca and Menorca, caves frequently are found containing burials rich in archaeological ceramics and glassy materials (Waldren, 1981; Amorós, 1974; Enseñat, 1981). Thus, the burial caves from Massana, Campanet, Mallorca (Frontan, 1991), and Cales Coves, Alaior, Menorca (Vený, 1982) are two good examples. They have produced ceramics and glass beads which give rise to several important questions about the cultural influences that have affected the Balearic islands in the past.

MATERIALS AND METHODS

Several glassy beads from the above mentioned burial caves have been selected for an archaeometric study by scanning electron microscopy and X-ray microanalysis.

Massana cave, Mallorca (Frontan, 1991), is located southwest of the mountain named Puig de la Mola near the village of Campanet. The cave's deposit is 2 m. thick and constituted by lime burials. Glass beads are located throughout the deposit both in earlier and later levels. Blue glass beads are located in the lower level which dates to the IVth century B.C. White and pyramidal glass beads and beads with dolphin shape are found in the upper levels and are dated approximately to the IIInd century B.C. Plate I shows the glass beads which we have analyzed from the Massana cave. The two views separated by arrows are of a bead with inlaid grains.

Cales Coves, on the coast of Menorca, are caves with burials cut into the limestone. The glass beads are found throughout the burials and possibly belong to different necklaces. They are found with bracelets, iron knives, bronzes, and rings and date to the IIIInd century B.C. Plate II shows the appearance of the small glass beads analyzed here. The two samples consist of the beads in the upper and lower rows.

They are either brown in colour with blue circles or, more frequently, they have a silver plate surface with a metallic aspect.

The four samples have been broken, their surfaces have been cleaned with ethyl alcohol and mounted with carbon glue in sample holders for scanning electron microscopy (SEM). Energy dispersive X-ray analyses (EDX) were performed in order to determinate the chemical composition of these ancient glass beads.

The SEM/EDX configuration used here has been a SEM/EDX digitalized microscope, Zeiss DSM-950, and a EDX Tracor Northern series Z-II spectrometer. For best comparison of chemical composition, average microanalysis results at lower magnifications have been carried out in exactly the same conditions for each specimen. Semiquantitative analysis were made by using the ZAF correction software from Tracor (McCarthy, 1979).

Plate I. Glass beads from the Massana cave, Mallorca, here investigated.

Plate II. Glass ancient beads from the Cales Coves, Menorca, here investigated.

RESULTS AND DISCUSSION

As is shown in Table I, the Massana glass bead including small quartz inlays in the surface is a high lead content glass, while the Massana grey glass bead is a lime-silica glass with high silica content. This grey glass has a high content of iron oxides (7.31 wt % expressed as Fe_2O_3). Therefore, although they are found in the same cave, these glass beads probably have different origins.

With respect to the Cales Coves glass beads there also exist differences. The silvered samples

are soda-lime-silica glasses containing an important proportion of lead (7.48 wt % PbO) and iron (5.55 wt % Fe_2O_3). Without considering this lead and iron content this glass could be similar to roman glasses from the Iberian Peninsula, like those previously studied by Rincón (1984). However, the blue glass bead is a high calcia-silica glass very close in composition to the Massana grey sample. Copper is present in a small proportion; the iron content is similar to the silvered sample; and the Massana grey sample has a low sodium content. This low sodium content (≈ 0.09 wt %) could be related

T. P., nº 50, 1993

to leaching in the burial, as can be seen in the strongly etched surface by scanning electron microscopy (Plate III). Therefore, in spite of its different colour and size, the grey glass bead from Massana is very similar in composition to the blue glass bead from Cales Coves.

TABLA I
EDX AVERAGE ANALYSIS ON ANCIENT GLASS
BEADS FROM THE BALEAR ISLANDS

sample	Massana			Cales Coves	Cales Coves
wt%	quartz inlays	same etched	Massana grey	silver	blue
Na ₂ O	11.75	6.90	—	14.40	0.09
MgO	1.65	1.13	—	—	0.60
Al ₂ O ₃	0.89	3.05	6.16	3.59	7.81
SiO ₂	41.71	28.15	76.13	56.43	73.86
SO ₂	—	—	—	—	0.53
PbO	39.83	54.06	—	7.48	—
K ₂ O	0.81	0.57	0.36	2.53	1.47
CaO	2.86	5.41	10.03	5.60	8.58
TiO ₂	—	—	—	1.98	0.37
Fe ₂ O ₃	—	0.22	7.31	5.55	6.48
ZnO	0.18	0.13	—	2.43	—
CuO	—	—	—	—	0.22

In conclusion, several glass beads from Mallorca and Menorca have been analysed by SEM/EDX. These glasses (grey, blue and silvered surfaces) belong to the general composition systems (wt % >5):

The composition of CaO glass beads is in some ways close to Roman glasses reported in previous papers. In terms of its lead content, the lead glass bead from Massana cave could be similar to Islamic lead glasses (Smith, 1969). In terms of MgO and K₂O, the Massana grey and Cales Coves beads would be Roman or early Islamic glasses (Smith, 1969). Nevertheless, more research is now in progress to elucidate aspects not yet clear in the investigation of these beads: the archaeological context of the beads reported by the excavator is earlier than the above-mentioned similarities would indicate.

ACKNOWLEDGEMENTS

Many thanks are due to P. Veny for making available the ancient glass samples for this study, and thanks also to M. Romero for his kind cooperation and A. Gilman for his review of the English.
